Field of the Invention The invention relates to the field of information processing technology and pertains particularly to a method and apparatus for operating a cable card in a cable modem. 2. Description of the Prior Art An important problem encountered in the design of communications networks is the translation of data from one format to another. For example, in the case of cable modems, the network headend uses a form of data communication known as "digital subscriber line" (DSL) and the cable modem connected to an end user uses "analog" techniques to communicate with the network headend. The cable modems typically include a modem chip and various transmission/reception circuitry. The cable modems are deployed in pairs. That is, the cable modem on the end user side is opposite the cable modem on the headend side. Similarly, the cable network headend is connected to a number of cable modems, each of which is located at a different place in a local telecommunication network, such as the Public Switched Telephone Network (PSTN). In a typical installation, the cable modems communicate with the telephone network by the use of an interface device known as the "Cable Modem Termination System" (CMTS). The CMTS is at the other end of the cable network headend and communicates with the cable modems by way of low data rate channels. The CMTS is intended to provide a "one-way" data path. That is, from the cable modems to the telephone network, but not in the reverse direction. In typical cable
