Google - Image - Google - Image. GetSaintAdministrativo. Descargar-Saint-Administrativo-Con-C. Descargar-Saint-Administrativo-Con-C1. Field of the Invention The present invention relates to an optical scanner apparatus and an image forming apparatus, and specifically to a technique of electrically controlling, for example, the phase of a deflector. 2. Description of the Related Art FIG. 13 is a schematic cross-sectional view of a conventional optical scanner apparatus. The optical scanner apparatus 1 illustrated in FIG. 13 includes an optical deflector 2 as a light beam deflector, a movable support table 3, a lens 4, a laser light source 5, a light detecting sensor 6, and a synchronous signal generator 7. The optical deflector 2 is a micro-type optical deflector that includes a light deflector and a mirror. The optical deflector 2 performs a light scanning operation by rotationally driving the mirror. Specifically, the optical deflector 2 can convert light beam spot P2 emitted from the laser light source 5 into a parallel light beam and deflect the parallel light beam P2 a predetermined angle so as to form the light beam spot P2 on an image surface 8. The movable support table 3 holds a polygon mirror 2a that includes an optical deflector 2 of the optical deflector 2, and is capable of moving in one direction. The movable support table 3 is rotated by a motor (not illustrated). In this way, light beam spot P2 can be sequentially transferred and scanned over a surface of a photosensitive recording medium, which is not illustrated, over a predetermined scanning line. In the present specification, a scanning operation of scanning a surface of a photosensitive recording medium with light beam spots is referred to as a scanning operation of performing an image forming operation, and the scanning operation of transferring and scanning the light beam spot P2 over the surface of the photosensitive recording medium with the optical scanner apparatus 1 is referred to as a scanning operation of performing a printing operation. The optical deflector 2 is disposed over a rotational center axis Y of the movable support table

One of the variables has a specific range, and I'm wondering what would be the best way to handle that. This is what I'm currently doing, but I need an idea of how to handle multiple ranges. var(1:4) = 1:4 for each i = 1:length(var(1:4)) if var(i) > 5 plot (i, var(i)) I was thinking of something like this, but that did not work. var = [var(1:4), var(1:5)] for each i = 1:length(var(1:4)) if var(i) 1cb139a0ed
