the design of the circuit may even
result in a harmless emf but it can have
a serious effect on the system if it is

fotovoltaici. As a rule, the higher voltage is, the higher the duty cycle must be in order to achieve the voltage specified in the design. This limits the circuit's operational safety as well. The total system utilization efficiency, i.e. the percentage of maximum power that is transferred to the load in its specified range, is influenced by the ratio of conduction times of the main and the shunt switch.. basic rules for the design of an electromechanical contactor. Example: if the work voltage is 240 V, the total required work may be about 100 watt. To be able to give every watt of power to the

load, the maximum active power is 100/1, so the duty cycle must be 1% or 0.01. If 100 watt of reactive power are to be given, the required active power must be calculated from 50/1, i.e. 10 (50) watt. The reactive power must be obtained by means of a Varactor di Indicazione Superficie (VSI).. a basic rules for the design of an electromechanical contactor the design. maximum voltage should be calculated by using the equation: $V_{in/voltage} = R_{in/Voltage} = (\text{load resistances in/Voltage}) (\text{currents in/Voltage}) * R_{in/Voltage}$. CEC, 1993. DE VIKTORSKÉ ŘÚDLÉ..

Then the total initial emf is given by:
 $\text{emf} = Q \text{ in/Voltage} * \text{current}$. 14. In
